

The prevalence of diabetes in Cook Islands adults was measured in the STEPS Survey.

- Participants were asked whether they had diabetes.
- To check (because some people have diabetes but do not know it), a blood test was taken to find the blood glucose level.
- All of the people who said they had diabetes and all of the people with raised blood glucose levels were grouped together to give the total number of people with diabetes.

1. What proportion of females aged between 35 and 44 years had diabetes? _____
2. What proportion of males aged between 45 and 54 years had diabetes? _____
3. Which gender (males or females) are more likely to have diabetes? _____
4. Which age group has the smallest difference between the proportion of males and females with diabetes? Approximately what is the difference?

5. Write two sentences to describe the main patterns that you can see on the graph.
