

# Introduction

In traditional Māori medicine (rongoā) Kawakawa (*Macropiper excelsum*) is used to treat a wide variety of ailments. It is considered to be one of the most potent medicinal herbs<sup>1</sup>.

There has been very little previous research into Kawakawa. Previous screening studies have indicated that Kawakawa had little anti-bacterial and anti-viral activity<sup>1,2</sup>. Evidence suggests that the extraction methodologies used in these previous studies were not the most suitable, as both used organic solvents<sup>1,2</sup> whereas traditional Māori preparation used water<sup>3</sup>. This could account for the disparity between what was observed in rongoā and the previous scientific studies. There has been no previous research into Kawakawa’s anti-inflammatory properties.

This study sought to investigate the disparity between the anecdotal evidence in rongoā and the scientific evidence available. It was hypothesised that Kawakawa will have anti-inflammatory activity, providing scientific support for the its use in rongoā.

# Conclusions

- Kawakawa has anti-inflammatory activity at specific concentrations of aqueous extract. The results show that:
- Anti-inflammatory activity was only observed in the aqueous extract.
  - The aqueous extract caused a dose-dependent decrease in nitric oxide, TNF-α and Il-6 production.
  - Nitric oxide production was suppressed at concentrations of 1000 µg/mL and 500 µg/mL
  - The inhibition of Il-6 production was maximal at extract concentrations of 1000 µg/mL and 500 µg/mL.
  - This inhibition of TNF-α production was maximal at extract concentrations of 250 µg/mL and 125 µg/mL.

Many of the traditional uses of Kawakawa could be linked directly to inflammation (such as toothache, irritation, serious bruises)<sup>3</sup>. The anti-inflammatory actions of Kawakawa could mask the symptoms of ailments not directly associated with inflammation (such as viral infections).

This study fills a niche in the literature as there been no previous research into the anti-inflammatory properties of Kawakawa, nor has any other research provided a scientific basis that supports the actions of Kawakawa in rongoā. Therefore, the uses of Kawakawa identified by Māori in rongoā are supported by the anti-inflammatory activity observed in this study.

# Discussion

- With regards to the extractions:
- Only the aqueous extract demonstrated anti-inflammatory activity.
  - This methodology best represented traditional Māori methods.<sup>3</sup>.
  - The extractions suggest the compounds responsible for the bioactivity are thermostable and polar.
  - The evidence suggests that the extract contained a variety of active compounds as it acted as both a pro and anti-inflammatory agent in some assays.
  - This suggests that the results arise from interactions between pro and anti-inflammatory compounds.

- Acute inflammation is associated with the production of reactive oxygen species such as nitric oxide, which is considered to be a key inflammatory marker:
- There were reductions in the nitric oxide production at the two highest concentrations of the aqueous extract (figure 1).
  - This suggests that the activity is dose dependant.

# Results

A positive result is a reduction in the value compared to the control. A reduction in nitric oxide, TNF-α and Il-6 production would be indicative of anti-inflammatory activity. This was observed in the aqueous extract. \* Indicates statistical relevance (P <0.05). Statistical significance calculated using a T-test. 0 µg/mL of Kawakawa extract was the control in all samples. Error bars show the standard error of the mean.

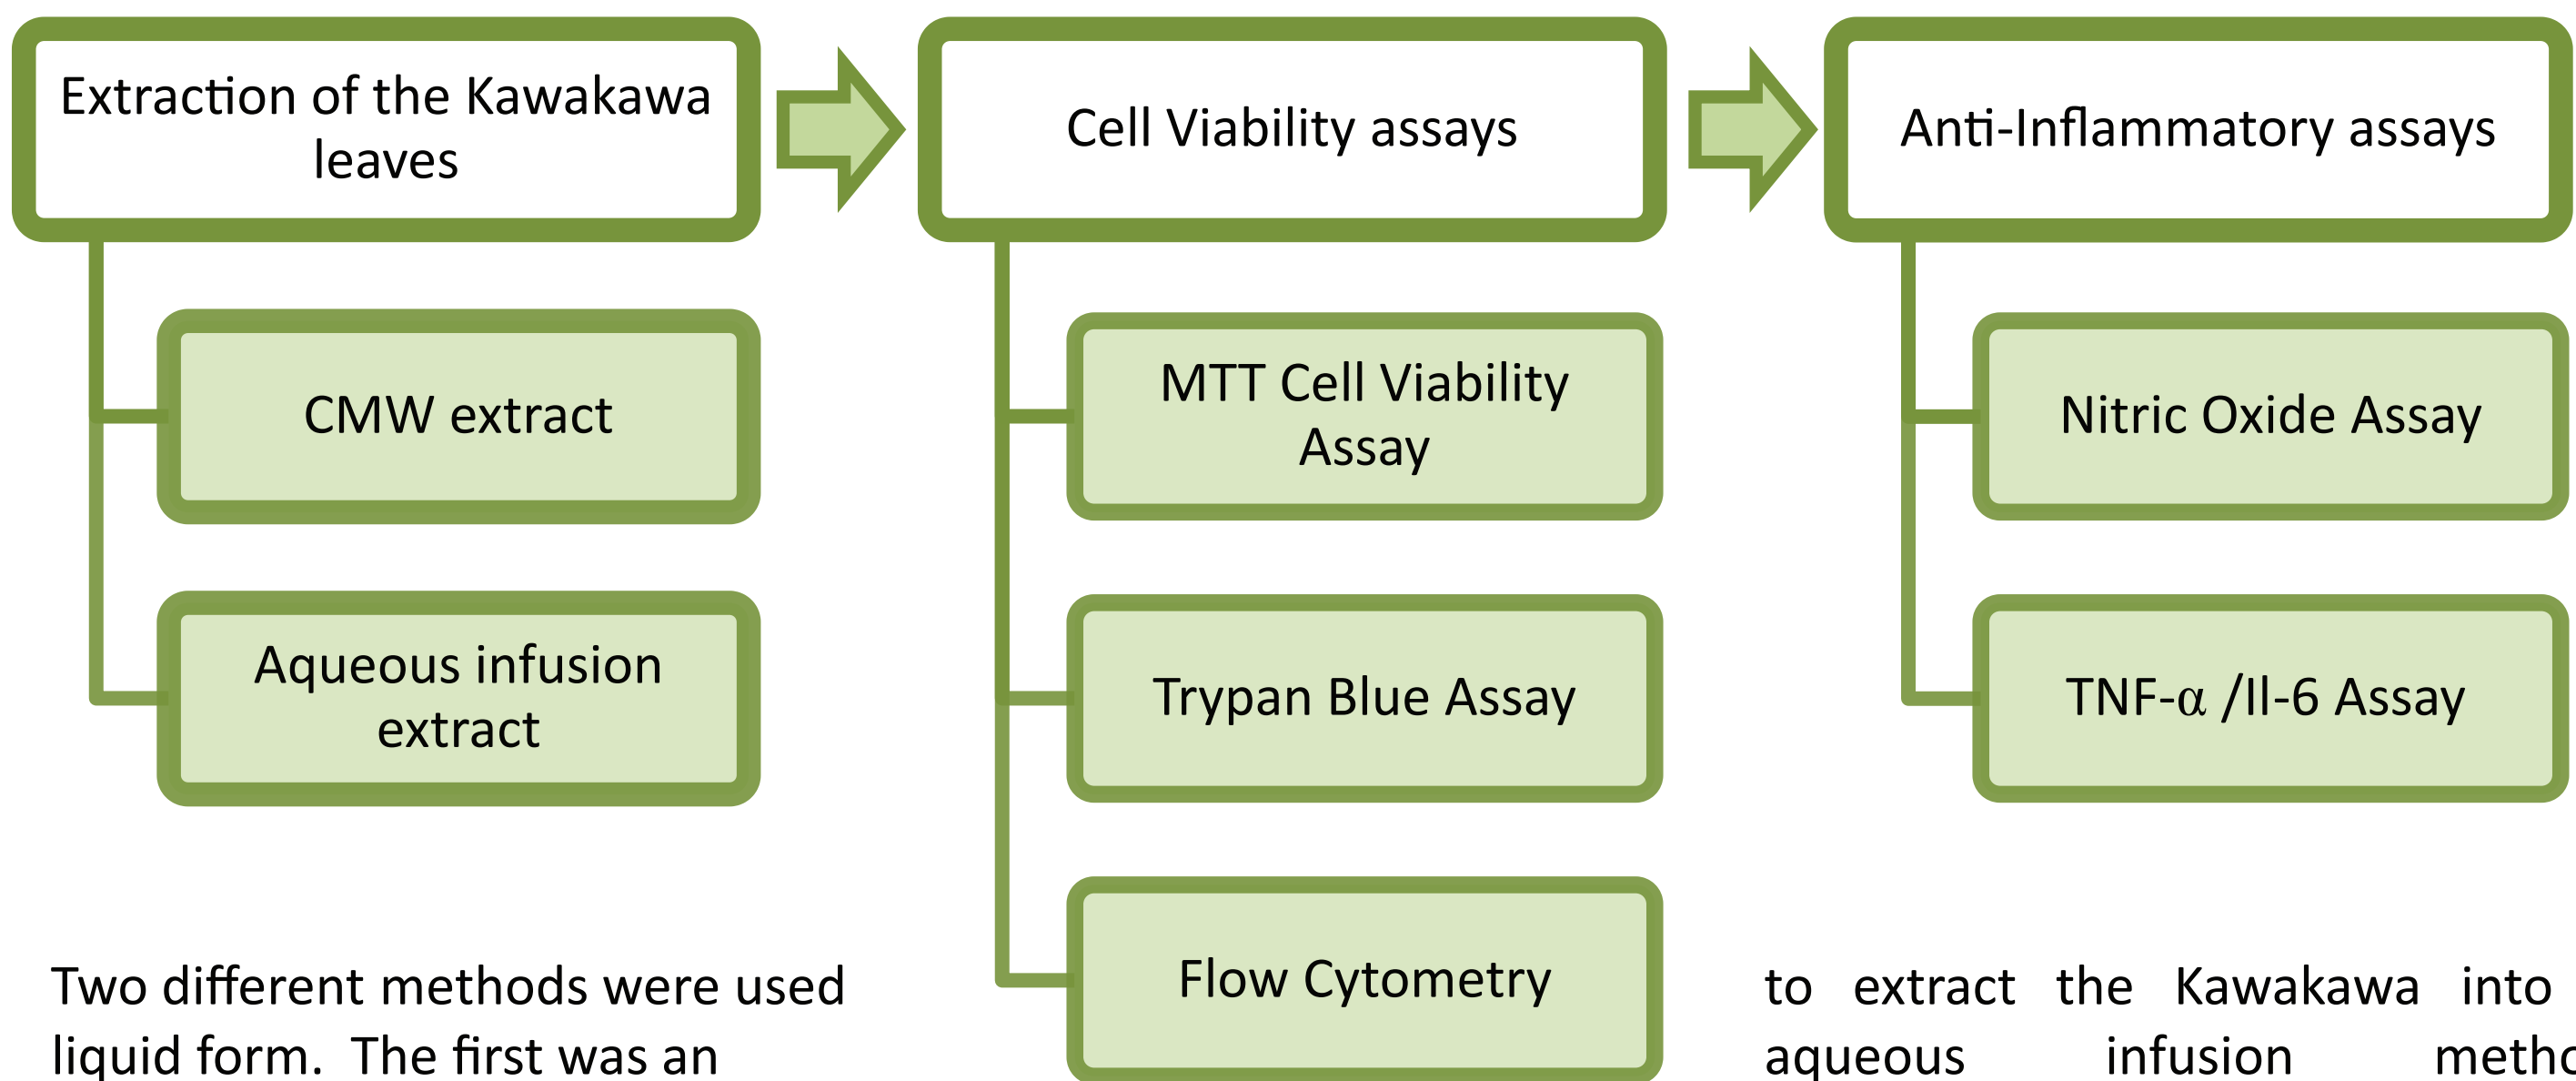

Figure 1: Nitric oxide produced in a variety of Kawakawa extracts: Reductions in the aqueous extract at the concentrations of 1000 µg/mL, and 500 µg/mL.

Figure 2: Il-6 production in cells exposed to the aqueous infusion extract: Reductions in the aqueous extract at the concentrations of 250 µg/mL and 125 µg/mL.

Figure 3: TNF-α production in cells exposed to the aqueous infusion extract: Reductions in the aqueous extract at the concentrations of 1000 µg/mL and 500 µg/mL.

# Methodology

Two different methods were used to liquid form. The first was an (analogous to making a tea) and In the second, leaves were soaked in chloroform-methanol-water (1:2:1 volume to volume).

The extract was tested for cytotoxicity in cell viability assays and then the non-toxic concentrations were used in the anti-inflammatory assays.

to extract the Kawakawa into a aqueous infusion method similar to methods used in rongoā.
