

Ambient versus Forced Vibration Modal Testing of Buildings

Sherif Beskhyroun
EQC Research Fellow

UACEER Symposium
28 November 2012

Modal Parameters

Full Scale Modal Tests

- Forced vibration tests
- Ambient vibration tests

Test Structure

- Layout
- Instrumentation

Identification Results

- Frequencies
- Damping
- Mode shapes

Finite Element Model

Conclusions

Modal Parameters

- Natural frequencies
- Damping ratios
- Mode Shapes
- essential task in the course of seismic design of civil engineering structures
- understand and interpret structural response during strong earthquake ground motion
- compare observations with theoretical results.

Tacoma Narrows Bridge

Damping ratio and natural frequency

Mode Shapes

Forced vibration tests:

- Vibration induced by external force
- Effective in obtaining accurate estimation of higher modes
- Expensive, time consuming to conduct and often require special permissions

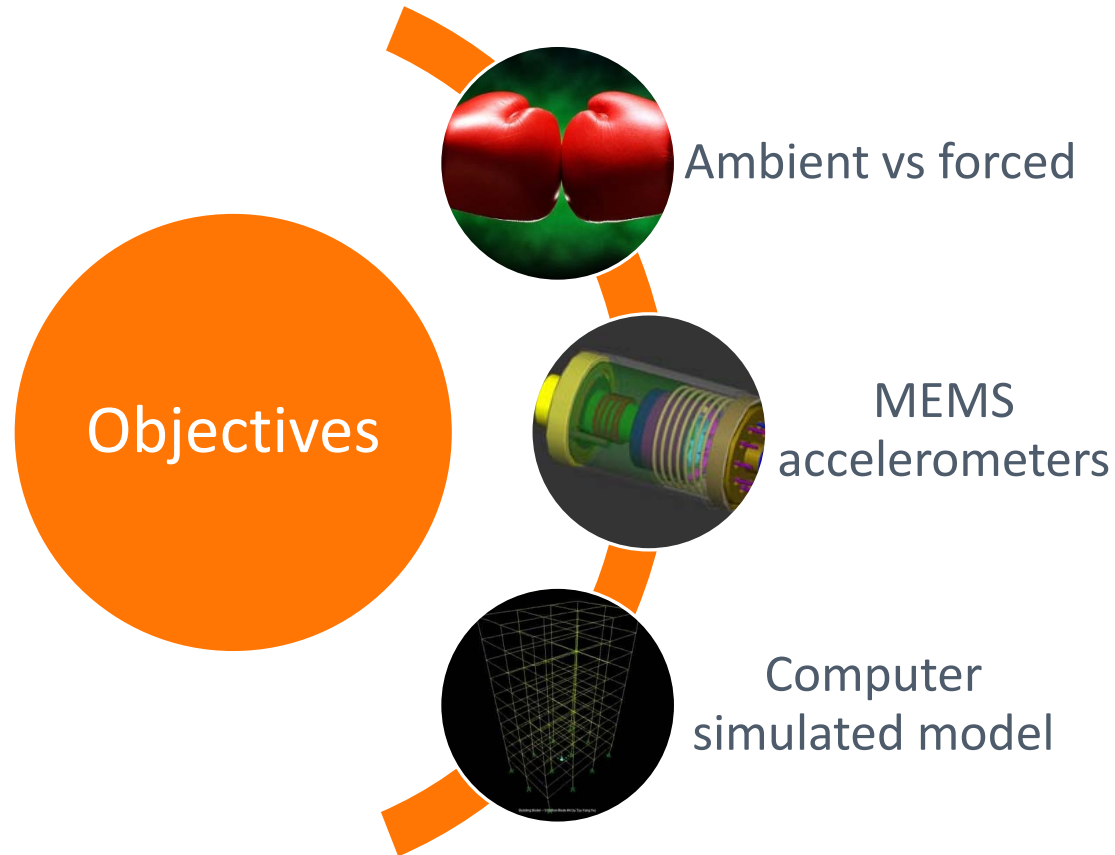

Eccentric Mass Exciter

Ambient vibration tests:

- Vibration induced by wind, traffic, operational use.
- Economical, non-destructive, fast and easy to conduct.
- Low signal to noise ratio.

Operational Use of Building

- 13 storey office tower
(Engineering Building 401, UoA)
- Constructed in 1964
- Height 40.54m
Plan dimensions 18.3m x 18.3m
- Structurally separate the
adjoining 3-4 storey buildings

Engineering Office Tower (401)

Eccentric mass shaker

$$F = m_e e \omega^2 \cos \omega t$$

m_e is the resultant eccentric mass of the exciter,
 e is the eccentricity of the exciter's eccentric masses,
 ω is the driving frequency (rad/s).

Resultant eccentric mass (per set)	Contributing eccentric weights		Eccentricity y (mm)	Max driving frequency	Force Amplitude
	Outside drums	Middle drum			
10 kg	2 - 2.5 kg	5 kg	325	9.0 Hz	13 kN (or 26 kN peak to peak)
20 kg	2 - 5 kg	10 kg		6.75 Hz	
40 kg	2 - 10 kg	20 kg		4.5 Hz	

Instrumentation

a) Forced vibration test

Accelerometers

Measurement range: ± 0.25 g

ADC: 12 bit

Low pass filter: 20 Hz

No of accelerometers: 6

LCF-100-14.5 servo accelerometers

(a) Position of accelerometers at levels 14, 13, 10, 7 and 5

(b) Position of accelerometer at level 2 (Ground level)

Figure 5.10: Position of accelerometers - Translational modes for the mode shape test.

(a) Position of accelerometers at level 13 - Torsional modes

(b) Position of accelerometers at level 7 - Torsional modes

(c) Position of accelerometer at level 2 (Ground level)

Figure 5.11: Position of accelerometers - Torsional modes for the mode shape test.

Micro-Electro-Mechanical System (MEMS) Accelerometers

Measurement range: ± 2.0 g

ADC: 16 bit

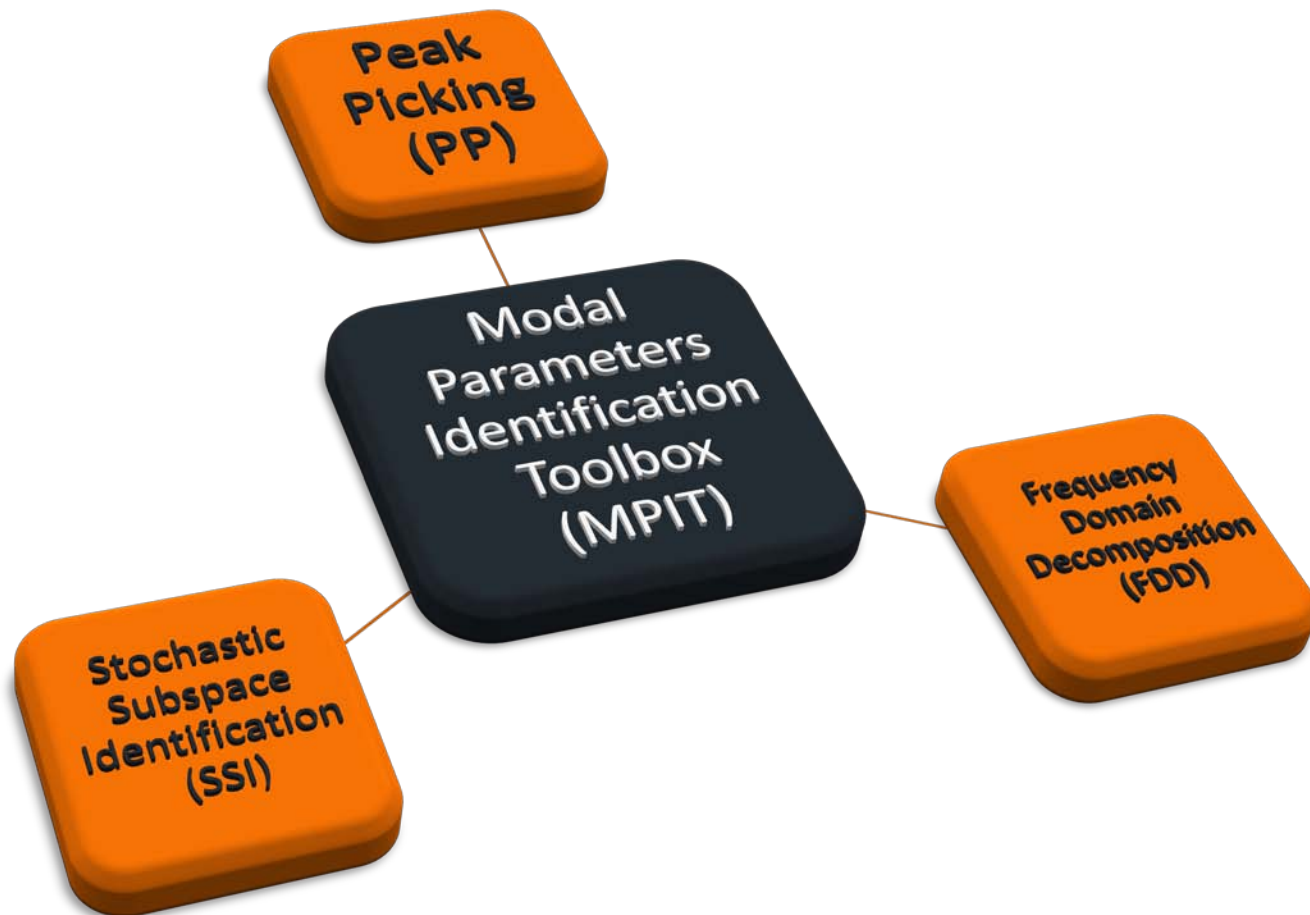

No of accelerometers: 49

Sampling rate: 40Hz

Test duration: 3 weeks

Modal Parameters Identification

Earthquake

Magnitude: 7.1
Depth: 230 km
Distance: 350 km
Date: 3 July 2012
Time: 22:36

Legend

- Depth less than 40 km
- Depth between 40 km and 69 km
- Depth between 70 km and 99 km
- Depth between 100 km and 149 km
- Depth between 150 km and 199 km
- Depth between 200 km and 299 km ←
- Depth greater than 300 km
- Magnitude less than 3.9
- Magnitude between 4 and 4.9
- Magnitude between 5 and 5.9
- Magnitude between 6 and 6.9
- Magnitude greater than 7 ←

1.803 Hz (1.836 Hz)

First torsional mode
2.5 Hz (2.461 Hz)

- Ambient vibration tests have proved that a small force can be used effectively to get the global modes of vibration.
- Very good correlation was observed between modal parameters from forced and ambient vibrations tests.
- Low cost MEMS accelerometers were successfully utilised to measure very small response amplitudes. The recorded data produced accurate estimates of the modal parameters.
